

# **Project Scanerio**

#### 1. Set Up the Project

 Create a new ReactJS project. Set up the folder structure, including a src/apiagents folder where you will store your mock API data.

#### 2. Create the API Agents

- In the apiagents folder, create a file where you will hardcode data in the form of an array of objects.
- Write async functions that simulate API calls by returning this hardcoded data after a delay.
- Export these functions for use in other parts of the project.

#### 3. Set Up Components

- Create multiple React components to display the data.
- Use useEffect in your components to call the async functions from the API agents and store the returned data in the component's state.
- Make sure to pass the fetched data as props to child components for display or further processing.

# 4. Manage State

- Use useState to manage the data in the components.
- Ensure that data is fetched and updated correctly when the component mounts.

# 5. Implement Prop Passing

- Pass data between parent and child components using props.
- · Structure your components to ensure data flows properly, demonstrating an understanding of how props work in React.

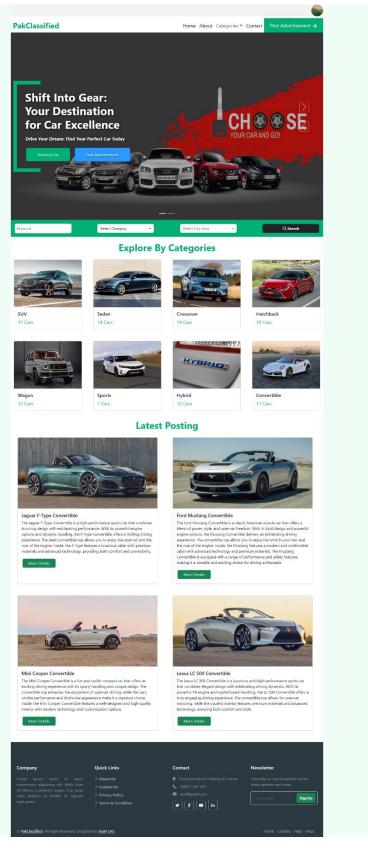

# Home Screen with user Login:

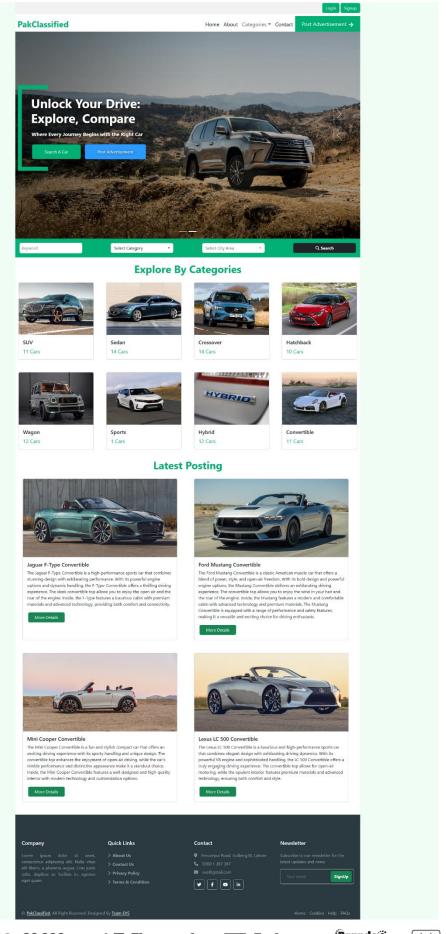

# **Home Screen** without Login

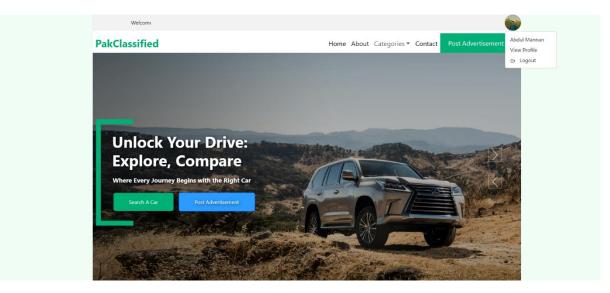

## **Component-1(Navbar)**

In the navlink it contains the categories section which we are fetching form the api the function will call on click and it will show in a dropdown

## (Navbar...)

By clicking on the user profile icon it will show some options as a dropdown which will be used to logout the user and show the user profile page

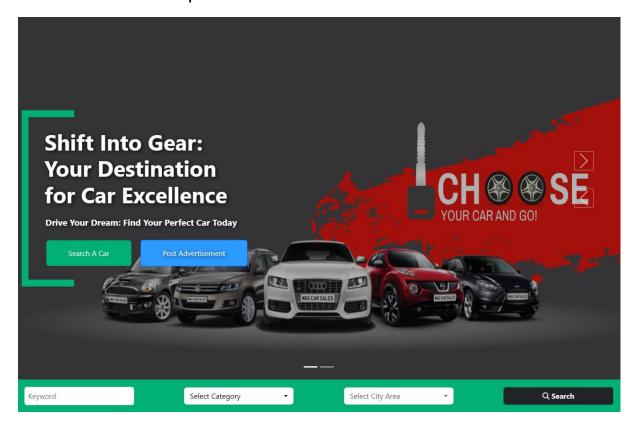

# **Component-2(Carousel)**

The carousel component contains two buttons one search advertisement on click on the show advertisement it will move the search bar which is place below the carousel

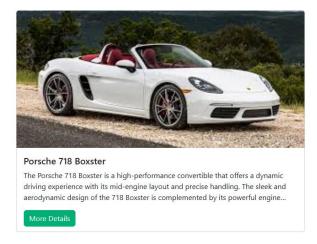

#### **Component-3 (Search with carousel component)**

It uses the bootstrap collapse component to whow the result on click the more detiaos button it will redirect to card-details component. Ther will be three options to search on the basis of name on the basis of category on the basis of city are we can use this together and alos we can use one of any seperately like if e want to search on the basis of just keyword then it will just take the keyword value from the user and show data. Alos all the category will be shown in the searchbar componet will be fetched from the databse it will also allow the user to search only on the basis of the category in the last the city area will also be fetched from the databse and it will allow the user to filter only those results on the basis of the that city area and when the user press it the search button it will show all the advertisement

#### **Search Results**

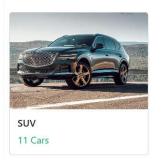

## **Component-4(Categories)**

It contains cards of each category by click on a specific category it will redirect to the category's component in which all the cars of that category will be shown. Also, there is a filter how many cars are there in the database of each category.

# **Explore By Categories**

14 Cars

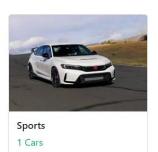

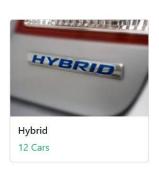

14 Cars

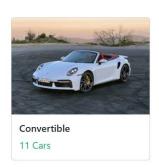

10 Cars

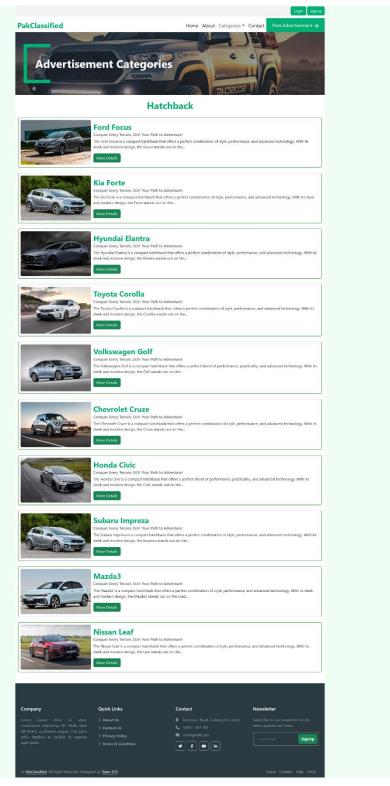

# **Component-5(Categories Component)**

Upon clicking on the category it will redirect to the advertisement categories below is the demo example

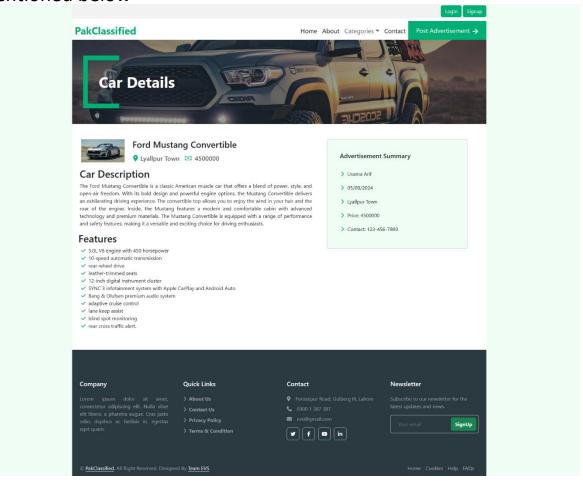

# **Component-6 (Car Details)**

By clicking on the more details button which is showing in categories section it will redirect to this component which is car details mentioned below
